An actuator-based latching/delatching mechanism 5 combination with an optical module includes a housing having a 6 front face with an opening and an optical transceiver designed 7 to be nestingly engaged in the opening. A front surface of the transceiver is flush with the face of the housing in a fully 8 9 nestingly engaged orientation. A pivot arm is pivotally 10 mounted adjacent a rear end of the housing for pivotal movement between a latching orientation in which the transceiver is 11 fully nestingly engaged in the housing and a delatching 12 13 orientation in which a force pivots the arm against the 14 transceiver to move the transceiver out of the 15 orientation. An actuator, with an end accessible exterior of 16 the housing, is mounted in the housing for movements from 17 latching to delatching orientations in response to a force 18 applied to the end of the actuator.
